

Simulation and Animation of Fire

Presentation in Seminar on

Physically-based Methods for 3D-Games and Medical Applications

Denis Steinemann

Denis Steinemann - Simulation and Animation of Fire

Motivation

What is fire?

- Fuel undergoing a chemical reaction and being converted into hot gas
- hot gas moves opposed to gravity and follows external wind
- essentially methods model hot gas

Why simulate fire?

- Dangerous, not easy to control in real-world
- sometimes, it is impossible to create a real-world model (for example, how does fire propagate in a building?)

3

- adds visual realism to 3D-Applications
- Games, movies

Discussion

Denis Steinemann - Simulation and Animation of Fire

Methods: Requirements

- realistic appearance
- user should be able to interact with fire
- fire spreads in space
- scalability: method should work for small and for large fires
- controllable, easy to handle user-parameters
- trade-off:

concentration on realistic visual behavior, but faster

 \longleftrightarrow

physically correct, very realistic, but also very slow

Denis Steinemann - Simulation and Animation of Fire

4

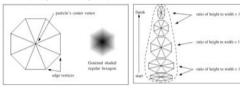

Methods (1): particle-based

Model fire using particles:

Hot gas as particles in user-defined velocity field u(x,t)

- Render particles (just some examples)
 - with polygons: change aspect ratio over time

5

Denis Steinemann - Simulation and Animation of Fire

Methods (2): fluid-based

Model fire using vector/scalar fields described by partial differential equations (PDE) → Computational Fluid Dynamics (CFD):

- usually three fields:
- Velocity u(x,t)
- for water & smoke, these two suffice • Density $\rho(\mathbf{x},t)$
- Temperature $T(\mathbf{x},t)$
- fields described by Navier-Stokes equations:

$$\begin{aligned} \frac{\partial \mathbf{v}}{\partial t} &= -(\mathbf{v} \cdot \nabla)\mathbf{v} + \nu \nabla^2 \mathbf{v} + \mathbf{f} \\ \frac{\partial \rho}{\partial t} &= -(\mathbf{v} \cdot \nabla)\rho + \kappa \nabla^2 \rho + S \\ \frac{\partial T}{\partial t} &= -(\mathbf{v} \cdot \nabla)T + c \nabla^2 T + H \\ &= \text{advect diffusion sources (user-defined)} \end{aligned}$$

Denis Steinemann - Simulation and Animation of Fire

Methods (1): particle-based

Warped-blobs technique: change shape of particle over time

Particle-based methods:

- Advantages: quite fast, realistic
- Disadvantages: need many particles; fuzzy outlines

- Demos
 - Stam

Denis Steinemann - Simulation and Animation of Fire

Methods (2): fluid-based

- Navier-Stokes equations hold for any fluid
- for fire, we also need temperature, because it determines the color of the fire (wavelength of light depends on temperature)
- Solve equations (expensive!); update fields using Euler, etc.
- the *density* field is rendered, using temperature to determine color (yellow fire, blue fire, smoke?)
- Rendering by Raytracing
- Advantages: physically correct, very realistic; shows smoke
- Disadvantages: very slow (5min per frame), complex handling
- Demos:
 - Fedkiw

Denis Steinemann - Simulation and Animation of Fire

Methods (3): flame-based

- single flame as fire primitive
- represent fire as a set of flames
- Advantages: faster (avoid solving very costly PDE), scalable, realistic, sharp outlines
- Disadvantages: not physically correct (concentration on visual behavior), not as realistic as with CFD

Denis Steinemann - Simulation and Animation of Fire

9

Flame-based simulation of fire

- I will now explain a flame-based method in detail
- Paper:

Realistic and Controllable Fire Simulation Philippe Beaudoin, Sébastien Paquet, Pierre Poulin Université de Montreal

- Divide simulation of fire into 3 subproblems:
 - Fire propagation
 - Flame genesis and animation
 - Rendering and modelling

Denis Steinemann - Simulation and Animation of Fire

10

Fire propagation

- Main visual feature in fire propagation is growth of burning zone
- Growth depends on an few locally defined parameters:
 - Fuel density
 - Oxygen supply
 - Surface orientation relative to gravity

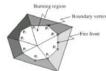

Our goal is to track the boundaries between parts of an object that are burning and those which have not yet been reached by the fire

Denis Steinemann - Simulation and Animation of Fire

Fire propagation

- Use closed curve on an object surface
- very often, surface is a closed triangle-mesh → closed curve represented as a broken line

broken line will never leave the

- Boundary vertices have
 - Position x(t)
 - Velocity v(x,t), depends on local params (fuel, surface orientation)
- Initial state: many vertices at ignition point, but each with a different vinit pointing radially outward in plane of initial face

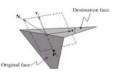

Denis Steinemann - Simulation and Animation of Fire

13

Fire propagation

- in all cases, the following hold:
 - Direction of velocity does not change when origin and destination faces are coplanar
 - **v**_i' is nonzero and oriented away from the crossed edge
 - continuity of curve is preserved

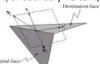

Denis Steinemann - Simulation and Animation of Fire

15

Fire propagation

• Given \mathbf{v}_i of boundary vertex i, compute new position \mathbf{x}_i :

 $\mathbf{x}_{i}(t+h) = \mathbf{x}_{i}(t) + h \cdot \mathbf{v}_{i}(t)$

- two possible cases:
 - $\mathbf{x}_i(t+h)$ lies on same face as $\mathbf{x}_i(t) \rightarrow ok$
 - **x**_i(t+h) lies outside of the face
 - \rightarrow adjust $\mathbf{x}_{i}(t+h)$, using new velocity \mathbf{v}_{i}

$$\mathbf{v}_{i}' = \eta(\mathbf{N}_{i} \times \mathbf{v}_{i}) \times \mathbf{N}'$$

- **v**_i: orig. velocity; **N**_i: linearly interpolated normal at crossing point
- η chosen to preserve magnitude of velocity
- N': normal to destination face

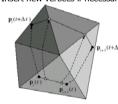

Denis Steinemann - Simulation and Animation of Fire

14

Fire propagation

- Burning zone grows over time → boundary expands with each time step
 - → 2-step update:
 - 1. Move vertex according to velocity, changing direction of ${\bf v}$ if necessary
 - 2. Insert new vertices if necessary to force curve to stay on surface

compute new vertex by using binary search to find point on original line that is displaced directly onto edge (velocity interpolated from endpoint velocities)

Denis Steinemann - Simulation and Animation of Fire

Fire propagation

- Boundary vertices may become sparse/dense → insert/delete vertices if that's the case
- v_i is defined by local parameters. Allow only change in magnitude of v_i, not in direction, so that the burning zone doesn't shrink
- in the next step, we will also need points inside the burning region

 \Rightarrow for a given line segment, displace random point on segment just like boundary vertex, but with interpolated velocity and a time

Denis Steinemann - Simulation and Animation of Fire

Discussion

Denis Steinemann - Simulation and Animation of Fire

Fire propagation

- Evolution of a (fire) front:
 - Relatively complex cow model; 5804 triangles

[Beaudoin, Paquet, Poulin]

Demos: Beaudoin

Denis Steinemann - Simulation and Animation of Fire

18

Flame Genesis and Animation

Now that we know how fire propagates on a surface, it's time to generate and animate the actual fire:

- single flame as fire primitive
- represent fire as a set of flames
- Flame = stream of gas that follows the air surrounding it
 - → Represent a flame as a chain of connected particles that moves according to some user-defined air velocity field. This chain is called skeleton.

skeletons dancing in the wind

Denis Steinemann - Simulation and Animation of Fire

Flame Genesis and Animation

- 5 steps to set up flame skeletons:
 - 1. define air velocity field
 - 2. plant flames on surface
 - 3. define flame skeletons
 - 4. grow/shrink flames
 - 5. allow for detached flames

Denis Steinemann - Simulation and Animation of Fire

21

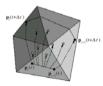

23

Flame Genesis and Animation

2. Plant flames on surface, inside burning zone

 use extra points inside burning zone that were additionally created during the evolution of the fire front

vary intensity of fire by varying density of points inside burning zone

Denis Steinemann - Simulation and Animation of Fire

Flame Genesis and Animation

1. Define an air velocity field V(x,t)

- User-defined
- general form:

$$\mathbf{V}(\mathbf{x},t) = \sum_{i=0}^{n} b_i(\mathbf{x},t) \mathbf{V}_i(\mathbf{x},t)$$

- b_i blending function; constant or smoothly in [0..1]
- lets user treat specific features of animated fire separately by giving each V, certain characteristics
- an example: $V(\mathbf{x},t) = -k\mathbf{g} + V_L(\mathbf{x},t) + V_S(\mathbf{x},t)$

k**g** lar

large-scale wind-field V_L

small-scale turbulences Vs

Denis Steinemann - Simulation and Animation of Fire

22

Flame Genesis and Animation

3. Define flame skeleton

- we have: root **s**₀ of flame
 - velocity field **V**(**x**,t)
- we want: curve segment $\mathbf{s}(\mathbf{u})$, every point tangent to instantaneous $\mathbf{V}(\mathbf{x})$

• $\mathbf{s}(\mathbf{u})$ is the solution of the differential equation $\mathbf{V}(\mathbf{s}) = \frac{d\mathbf{s}}{du}, \mathbf{s}(0) = \mathbf{s}_0$

Denis Steinemann - Simulation and Animation of Fire

Flame Genesis and Animation

- in general, **s**(u) is hard to find analytically
- skeleton is a broken-line approximation of **s**(u)

- solve numerically using Euler
 - skeleton vertices: s_i = s(u_i)

$$\mathbf{s}_{i+1} = \mathbf{s}_i + \frac{l(t)}{n} \mathbf{V}(\mathbf{s}_i)$$

- n predefined, (n<10); n+1 = # of vertices in skeleton</p>
- *l*(*t*) determines length of skeleton (see later)

Denis Steinemann - Simulation and Animation of Fire

25

Flame Genesis and Animation

4. Grow and shrink flames

- for realistic behavior, flames are newly created and may disappear after some time
- for this, use length function l(t)
- length function depends mostly on fuel (→ "fuel map" on surface)
- examples:

t

explosive, fast burning

 vary peak of length function for different flames to make fire look more realistic

Denis Steinemann - Simulation and Animation of Fire

27

Flame Genesis and Animation

- Problem: skeleton may penetrate object, because V(x,t) does not consider geometry
 - \Rightarrow adjust vector field locally by adding vector ${\bf N}$ normal to the surface at root ${\bf s_0}$

|N| large enough for s_i to be outside of object

Denis Steinemann - Simulation and Animation of Fire

26

Flame Genesis and Animation

- technique described so far works well for guiet flames
- in highly turbulent fires, flames can take off into the air, drift upwards for some time and then disappear

5. Detach flames

- if at a vertex \mathbf{s}_i of a skeleton, $|\mathbf{V}(\mathbf{s}_i)| > threshold$
- insert new flame whose root s_0 equals s_i and is free
- the root then can move with the velocity field in time, updated at every time step:

$$\mathbf{s}_{0}(t+h) = \mathbf{s}_{0}(t) + h \cdot \mathbf{V}(\mathbf{s}_{0}(t),t)$$

■ Use new **s**₀ to create entire flame as before

-

Denis Steinemann - Simulation and Animation of Fire

- Since detached flames have short life span, adjust their length function
- Skeletons are well-suited for quick previewing, which speeds up the iterative process of obtaining the desired effects

[Beaudoin, Paquet, Poulin]

Flame skeletons on a burning sphere

Demos:

Beaudoin

Denis Steinemann - Simulation and Animation of Fire

29

Rendering and Modelling

Skeletons are good for previewing, but they are not sufficient for photorealistic rendering

- \rightarrow dress up the skeletons
- 4 steps:
 - 1. Define implicit surface which describes the outline of a single flame
 - 2. use implicit surfaces of single flames to model a complete fire
 - 3. model color variations seen inside fire
 - 4. render the final image

Denis Steinemann - Simulation and Animation of Fire

30

Rendering and Modelling

1. Define implicit surface

 physical analogy: electrical potential induced by a uniformly charged rod

 $E_i(\boldsymbol{x})$: "potential of \boldsymbol{x} , induced by segment i of the skeleton"

$$\begin{split} E_i(\mathbf{x}) &= \int\limits_{p=0}^{d_i} \frac{1}{\sqrt{(p-z_i(\mathbf{x}))^2 + r_i(\mathbf{x})^2}} dp \\ &= \sinh^{-1} \left(\frac{z_i(\mathbf{x})}{r_i(\mathbf{x})} \right) - \sinh^{-1} \left(\frac{z_i(\mathbf{x}) - d_i}{r_i(\mathbf{x})} \right) \end{split}$$

$$d_i = |\mathbf{s_i} - \mathbf{s_{i-1}}|$$

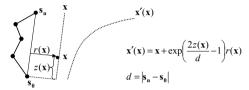

- z_i(x) and r_i(x): cylindrical coordinates of x relative to segment i
- for a complete flame, "potentials" add up: $E(\mathbf{x}) = \sum_{i=1}^{n} E_i(\mathbf{x})$

Denis Steinemann - Simulation and Animation of Fire

Rendering and Modelling

 Problem: E(x) does not distinguish between root and top of flame, but flames are thin at the top and bulged at the root
→ transform x to height-dependent x'(x):

- $\mathbf{z}(\mathbf{x})$ and $\mathbf{r}(\mathbf{x})$: cylindrical coords of \mathbf{x} relative to segment $(\mathbf{s}_0, \mathbf{s}_n)$
- use E(x'(x)) instead of E(x)
- near top of flame, $\mathbf{x}'(\mathbf{x})$ is farther away from the skeleton than $\mathbf{x} \to \mathsf{E}(\mathbf{x}'(\mathbf{x}))$ smaller than $\mathsf{E}(\mathbf{x}) \to \mathsf{iso}$ -surface closer to skeleton

Denis Steinemann - Simulation and Animation of Fire

33

Rendering and Modelling

- we have the *shape* of flames (and fire)
- now we also want color
- Color depends on temperature (fire emits radiation of different wavelength). Temperature in flame mainly depends on distance to base and to the center of the flame

3. Compute iso-surfaces to model color variation

- Compute iso-surfaces of I(x)
- → we get enclosed surfaces to each of which we can assign a color

use marching-cubes algorithm to obtain a closed (polygon) surface

Denis Steinemann - Simulation and Animation of Fire

35

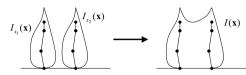

Rendering and Modelling

2. Use implicit functions to model complete fire

Putting it all together:

- Flame: $I_{\alpha}(\mathbf{x}) = E(\mathbf{x}'(\mathbf{x}))$
- Fire: $I(\mathbf{x}) = \sum I_{\varepsilon}(\mathbf{x})$

two iso-surfaces $I_{s1}(\mathbf{x}), I_{s2}(\mathbf{x}) = v$

new iso-surface $I(\mathbf{x})=I_{c1}(\mathbf{x})+I_{c2}(\mathbf{x})=v$

Denis Steinemann - Simulation and Animation of Fire

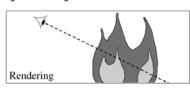

34

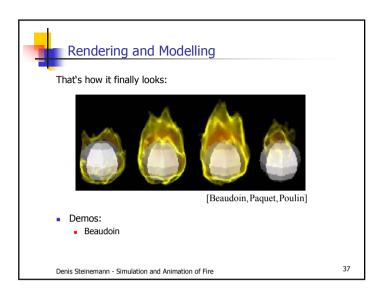

Rendering and Modelling

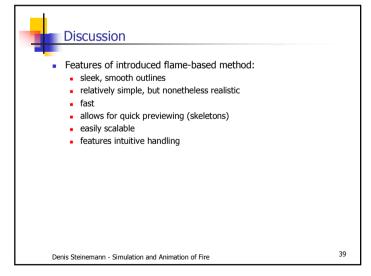

4. Render fire using iso-surfaces

- use raytracing (raycasting)
- cast rays toward polygons of iso-surfaces
 - → calculate length of a ray inside each layer
- add up color contributions from different layers for each ray
- omit light-scattering inside fire

Denis Steinemann - Simulation and Animation of Fire

Results

- Surfaces with a few hundred triangles, 400MHz, 256MB RAM
 - Propagation: 15 fps
 - Skeletion animation (100 skeletons): 4 fps
 - Complete with rendering: 4 frames per minute
- Not real-time, but compared to fluid-based methods, flame-based approach is much faster

Denis Steinemann - Simulation and Animation of Fire

38

Discussion

- Limitations:
 - Fire cannot spread to other, disconnected objects
 - → start new propagations on other objects
 - Rendering rather simple (no self-lighting, no illumination of other objects by fire)
 - no smoke
- Further Possibilities:
 - Charring draw a black splat on object surface when flame becomes extinct
